Incline Village, NV

Executive Summary:

This report is an examination of the electrical system as it is currently designed. The main service as well as emergency service systems were examined, including all lighting, mechanical, and other miscellaneous equipment. In order to analyze the building, data obtained from the drawings, specs and panelboard schedules were used in order to determine appropriate sizing for equipment. NEC requirements for sizing of circuit breakers, wiring and conduit were observed during the analysis. Also analyzed were the rate structure and limitations on electricity rate due to the photovoltaics and cogeneration unit.

After the analysis, it was determined that (as expected) the building was designed appropriately to meet the NEC design requirements. The switchboard was found to be about 250A larger (1600A designed vs ~1350A required) than required, but since 1600A is a common size for switchboards, its is likely not cost effective to change this with a switchboard closer to the actual design amperage.

Narrative:

System Type:

The building's electrical system is a radial type system. The service entrance contains only a single transformer and a primary feeder which then serves secondary panels and feeders.

Building Utilization Voltage:

The main service into the building is 208Y/120V. One possible point of investigation may be to try and redesign the system to utilize 480Y/277V.

Transformer Configuration:

Aside from the transformer at the service entrance, the only other transformer in the building is to connect the Cogen unit. It is a 30kVA, 480V to 208V step down transformer since the Cogen unit supplies 480V but the rest of the building is run on 208. In the redesign, it may be possible to change the main service from 208V to 480V, and since the only thing that would have to remain at 208Y/120V would be receptacle loads (since most mechanical and lighting equipment can be run at 480Y/277V) the transformer placed at the Cogen unit can be resized and moved to feed the receptacle loads, which would most likely lead to a minimal increase in cost.

Emergency Power Systems:

Lighting: Emergency ballasts are placed in specific light fixtures to maintain emergency lighting for up to 1 ½ hours.

Generator: 55kW, 208Y/120, Kohler model 50RZGB with a 4P8W alternator. It is capable of starting motor loads of 183kVA inrush with maximum voltage dip of 35%. Factory set startup time of 3 seconds. The generator feeds emergency panels "BC" and "3C" which contain fume hood loads. U.C. Davis required that fume hoods be back up and running within 30 seconds of a power outage, so the generator ensures that this is the case. No code required emergency loads are required to be on the generator branch since lighting is taken care of via battery packs.

ATS: 3 pole, 4 wire, 3 phase Kohler model KCT-ACTA-0200S with a 200A current rating a 208V-60hz rating and a solid neutral. Factory set delay of 1 second for transfer to standby power and factory set delay of 15 minutes for transfer back to normal power.

Narrative (cont'd):

Overcurrent Devices:

Circuit breakers are used on all panels and to protect all feeders.

Motors are protected by fused disconnects at the motor as well as circuit breakers when connecting to panelboards.

Locations:

Switchboard: 6000A SquareD SWBD "B" located in basement electrical room.

Panels: Each floor contains panels serving that floor, with additional distribution panels located in the basement.

Lighting Systems:

Fluorescent and Metal Halide lighting can be found throughout the building operating at 120V. A more efficient (from a distribution point of view) 277V lighting system may be investigated during redesign.

ASHRAE 90.1:

The main switchboard is protected by a 1600A circuit breaker. Each subsequent panel is protected by an appropriately sized circuit breaker corresponding to the size of the panel (see single line diagram).

Power Factor Correction:

None.

Special Design Requirements:

UC Davis placed a restriction on the design team as far as how fast the fume hoods in each lab space would be able to come back online. They wanted them to be back up within 30 seconds to avoid any harmful gases from being inhaled by the occupants. For this reason, the fume hoods were placed on panels fed by the emergency generator. Emergency lighting loads are taken care of via battery packs in emergency ballasts, so there are no loads required by code to be on the emergency generator.

Lamp Info:

Load Information:

Single Line Diagram:

See Attached or "P:\ae 481\tech2\single line.pdf"

Major Mech Equip:

See Attached or "P:\ae 481\tech2\mech.pdf"

Electrical Equipment:

See Attached or "P:\ae 481\tech2\elec.pdf"

Total Load:

Load Type	w/o Demand	Demand Factor	w/ Demand
Lighting	44.00	1.25	55.00
Motor	122.20	1.00	122.20
Receptacles	218.61	10k @1, >10k @.5	114.31
Largest Motor	30.00	0.25	7.50
Other Mech.	89.88	1.00	89.88
TOTAL kVA	504.69		388.89
TOTAL Amps	1400.88		1079.44

Main incoming service Feeder Sizing:

Allow for expansion: $1.25 \times 1079.44A = 1349.3A$

75 °C Copper wire used

From tables 310.16 and of the NEC: (5) sets of (4) 300MCM in 3" conduit, rated at 1425A

Analysis of existing switchboard:

Existing switchboard rated at 1600A

Design Amps = 1349.3A

Design Amps < switchboard rating, therefore **OK**

Utility Information:

Utility Rate Info:

TCES and the Cogen unit fall under the Qualifying Facility (QF) rate structure, as they are a small generating facility, The PVs are taken care of under a net metering agreement in which any surplus generated by the PVs rolls the meter backwards, with limits added stating that the meter may not be negative at the end of the month (i.e. any electricity generated beyond what is consumed from the grid is then “donated” back to the grid).

Additional Restriction/Considerations:

PVs alone

To qualify as a Net Metering customer and to possibly qualify for incentives, the PV system can not be larger than 30 kWac.

Installing a system larger than 30kWac allows for application to the Renewable RFP process by submitting an unsolicited bid for the sale of Renewable Energy Credits (RECs).

If the application is short-listed a power purchase agreement for the RECs, an interconnection agreement and a standby agreement must be agreed to. These agreements would be for 10-20 years and would include performance penalty provisions.

PVs and Cogen

Both installations will be required to have generation meters so the output of each can be determined.

The PV installation would be treated as if it were a Net Meter application, so a Net Metering Agreement must be agreed to.

The cogen installation falls under the CSPP tariff as a FERC Qualifying Facility and an interconnection agreement and a standby agreement would have to be agreed to.

Any excess energy generated from the combination of these systems will be treated as if it came from the cogen system and thus would fall under the CSPP tariff.
